

Edit the real text layer of a PDF. No OCR, no overlay.

What this page is

Every line you see is real text in this file's own text layer, not a picture of text and not a box drawn on top of it. Turn on Edit, tap a paragraph, and type. The glyphs on screen are the engine's own output.

Try these

- Edit this paragraph and watch the lines below it reflow to fit.
- Edit a heading instead. Headings keep their line; they do not reflow.
- Select a word and delete it. The spacing closes up as it should.
- Grow a word to 24 pt. The line spacing grows with it, both ways.
- Press Save. What downloads is a real PDF with your edits inside.

One line, two colours

This half of the sentence is teal, and this half is red.

Select across the join: a correct host shows a blank swatch, not one of them.

Engine	PDFium, compiled to WebAssembly
Editing	one C++ core, shared by web, Android and iOS
Colour	this value is amber, the label beside it is not
Sample	our own content and our own pictures, free to redistribute

The complex half

A centred block, three lines deep

so the alignment classifier has enough
members to call it centred at all.

*and this pair is right-aligned,
which is a different arm of the classifier.*

Two columns

These two blocks sit side by
side and share every baseline.
They must stay two paragraphs:
editing one may not pull a word
out of the other.

Five families

Helvetica sets this line.

Helvetica Bold sets this one.

Helvetica Oblique, this one.

Times Roman, a serif face.

Courier, monospaced.

Mixed sizes on one line

This word is **LARGE** and the rest is not.

A small table

Platform	Surface	Status
Web	JavaScript API	shipping
Android	PdfeEditorView	shipping
iOS	JSON bridge	shipping

Figure 1. Drawn pixel by pixel.

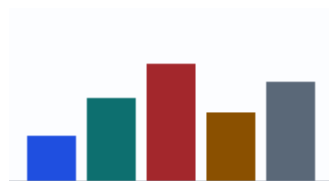

Figure 2. Flat colours, on purpose.

Both pictures are generated by the
script that writes this file. Neither
is editable text, and neither moves
when you edit the words beside it.
